

Technical Documents:

June 1. We underwent training on comprehensive endpoint management, secure data migration, and remote user support. We learned how to set up and perform the “re-ds” system imaging process for both laptops and desktops, as well as the protocols for securely transferring critical files over to our admin account. Additionally, we were trained on how to handle direct employee inquiries and establish remote connections to their laptops to perform disk cleanups on their C drives, clearing up vital storage space to boost system performance. This session was highly beneficial as it provided hands-on experience in both hardware provisioning and remote optimization, showing me how our team keeps company devices secure, efficient, and running smoothly from any location.

June 2. We were trained on advanced workstation management, secure data migration, and system maintenance workflows. Aside from setting up and executing the “re-ds” re-imaging process for both laptops and desktops, we practiced transferring critical files safely into our admin account and resolving general employee technical concerns. Additionally, we learned how to process a list of PC names from an Excel sheet to identify machines with outdated files, cross-reference them for repairs, and execute system patches to bring them up to date. This training was incredibly valuable because it taught me how to combine bulk data tracking with proactive software maintenance, ensuring all company endpoints remain uniform, secure, and fully optimized.

June 3. We underwent comprehensive training covering hardware deployment, remote maintenance, and network directory administration. We practiced setting up and executing the “re-ds” system imaging process for both laptops and desktop computers, along with securely migrating critical user files over to our admin account. A major focus of the session

was learning how to address direct employee inquiries, which included remotely accessing their laptops to perform disk cleanups that cleared up to 64GB of vital storage space. Additionally, we were trained on the crucial security step of managing asset lifecycles by locating and disabling decommissioned or unused employee laptops within Active Directory. This training was incredibly valuable because it showed me how hardware provisioning, remote optimization, and backend user access controls all work together to keep the company's network secure and efficient.

June 4. We were trained on the core workflows of workstation preparation and employee technical support. We learned how to efficiently set up and execute the "re-ds" system imaging process for laptops, as well as the protocols for securely transferring critical user files over to our admin account. Additionally, we practiced handling incoming employee service requests, learning the best ways to troubleshoot and resolve their hardware and software concerns when they reach out to our team. This session was incredibly practical because it combined backend technical deployment with active user support, giving me a solid foundation in how we maintain system standards and keep the company's daily operations running smoothly.

June 5. Our training focused on active employee helpdesk support and remote system maintenance. We practiced handling incoming technical concerns from employees who reached out to our team, learning how to efficiently troubleshoot and resolve their issues. A major part of the session involved learning how to establish secure remote connections to their laptops to perform deep disk cleanups, successfully clearing up to 64GB of unnecessary data to free up vital storage space. This experience was incredibly valuable because it showed me how to optimize device performance and resolve software slowdowns from a distance, ensuring our team members can continue working smoothly without technical interruptions.
